MPE FD/WD-E - User Manual

1. Introduction

The MPE FD/WD-E card interfaces the E-bus to Western Digital's WD-1002 series of floppy and hard disc controllers. These controllers can support four floppy disc drives and three Winchester disc drives with ST506 interfacing. Support for floppy discs only is available via MPE's forthcoming FD-E card.

2. Installation and Configuration

The card should be linked for the required memory address (MPE standard is 00.FF00), and then installed. The 40-pin ribbon cable should be taken to the host adapter connector on the WD-1002 card. This card has the same form factor and mounting holes as a standard 5" floppy disc unit, and so may be mounted on the drive. Power to the WD-1000 should be supplied separately.

The card is capable of generating a memory overlay signal, PHANTOM-, which MPE's memory cards can respond to. This signal disables memory on these other cards, so allowing only the space required for the interface to be lost.

2.1. Linking

Link	Function
1,2	not used
3	fit to enable INTREQ to INTEN- on E-bus
4	fit to enable DRQ to INTEN- on E-bus
5,9,10	not used
11	fit to enable FD/WD-E to generate PHANTOM-
12	fit to use E-bus AREADY- line (9900 only)
13	fit to use E-bus READY- line (9995 & 99000)
Int. Lev.	
0	spare - no interrupts generated
1	interrupt generated on PWRFAIL-
4	interrupt generated on INTEN-
Waits	
1	0 wait states
2	1 " "

3	2	"	"	(default for 3MHz 9995)
4	3	"	"	
5	4	"	"	
6	5	"	"	
7	6	"	"	

2.2. Address selection

The two DIL switches are used to select the required base address. MPE software uses 00.FF00 as a default, with PHANTOM- being generated to overlay the RAM-E card(s).

Switch	Address line (open=1)
SW1/1	XA0
SW1/2	XA1
SW1/3	XA2
SW1/4	XA3
SW1/5	A0
SW1/6	A1
SW1/7	A2
SW1/8	A3
SW2/1	A4
SW2/2	A5
SW2/3	A6
SW2/4	A7
SW2/5	A8
SW2/6	A9
SW2/7	A10
SW2/8	not used

3. Software

Sample software listings for a device driver are included at the rear of the manual. The listing shown is for a simple non-interrupt driven handler for the MDEX operating system.

The card occupies a 32 byte slot. Because of the requirements of 9900 and 9980/81 processors, which perform a read before a write, and the software constraints of the WD-1002 cards, it has been arranged that offsets 0-15 generate read accesses to the WD card, and 16-31 generate write requests. A15 is ignored. In 16-bit systems data will be transferred on the low byte of of the data bus (AD8-15). System software that has to be independent of processor type and data bus width should access the card by byte transfers on odd addresses.

4. Theory of operation

How the card works is discussed in three sections, address decode logic, wait state generation, and WD-1002 drive logic.

4.1. Address decode logic

Memory addresses are captured from the E-bus by two latches (IC 10 and 11), and applied to two linked octal comparators qualified by MEMEN-.

The required address is set up on the two DIL switches, SW1 and SW2. The enable output of the comparators is then fed to the wait state logic, the WD-1002, and the data bus buffers.

4.2. Wait state logic

The inverted enable signal is fed to the shift register (IC9, 74LS164) inputs and the PHANTOM- generator. The shift registor ouput is inverted and used as READY- or AREADY-. The shift register is cleared by ALATCH-.

4.3. WD-1002 driver logic

The data bus is buffered by a 74LS245 (IC7). Three latched address lines, AD12, AD13, and AD14, become the WD cards A2, A1, and A0 respectively. The WD-1002 control strobes, RE- or WE-, are generated and delayed slightly, for a true address decode and ALATCH low. A read strobe is generated for AD11 low, DEN- active (low), and WE- inactive (high). Conversely, a write strobe is generated for AD11 high, DEN- inactive (high), and WE- active (low). This arrangement prevents the FD/WD-E from accessing the WD card during the read cycle immediately before a write that is generated by 9900 and 9980/1 processors for any writes, and by 99000 processors during byte writes. The WD RESET- signal is a buffered version of the E-bus IORST- signal.

5. Connector

The connector to the WD card is a 40-way IDC connector. All the even numbered pins (2-40) are grounded.

Pin	Function
2-40	grounded
1	D0 (lsb)
3	D1
5	D2
7	D3
9	D4
11	D5
13	D6
15	D7 (msb)
17	A0 (lsb)
19	A1
21	A2 (msb)
23	ENABLE-
25	WE-
27	RE-
29,31,33	not used
35	INTREQ
37	DRQ
39	RESET-

6. Ebus pin-out

For full details of E-bus use and specification, see the 'E-bus System Design Handbook' published by Texas Instruments European Semiconductor Group, September 1981, TI part number MP402.

*1 6C is optionally redefined on some MPE cards (FD/WD-E and RAM-E) as PHANTOM-. This is an open collector signal terminated on the backplane that may be pulled low by any memory-mapped peripheral wanting to overlay memory. The memory card that that responds to this signal should treat it as an inhibit signal and, as a minimum, should disable its data bus buffers, and should not activate READY-. PHANTOM- should be asserted as soon as possible in a memory cycle. Use of this facility is made in systems where it is desired to have as much memory as possible, losing only the minimum possible space to memory-mapped peripherals. To take full advantage of this feature, we suggest that memory mapped peripherals be positioned at or above OFF00.
